# High-Resolution Laser Spectroscopy of Strontium Monomethoxide, $\mathrm{SrOCH}_{3}$ 

L. C. O'Brien, C. R. Brazier, and P. F. Bernath ${ }^{1}$<br>Department of Chemistry, University of Arizona, Tucson, Arizona 85721

#### Abstract

The rotational analysis of the $0-0$ band of the $\tilde{A}^{2} E_{3 / 2}-\tilde{X}^{2} A_{1}$ transition of the $\mathrm{SrOCH}_{3}$ free radical has been carried out by laser excitation spectroscopy. The $\mathrm{SrOCH}_{3}$ molecule was found to have $C_{3 v}$ symmetry with a Sr-O bondlength of $2.12 \AA$. There was no evidence of a Jahn-Teller effect in the $\tilde{A}^{2} E$ state. This work is the first high-resolution analysis of a metal alkoxide molecule. © 1988 Academic Press, Inc.

## INTRODUCTION

We have recently observed the gas-phase low-resolution ( $1 \mathrm{~cm}^{-1}$ ) spectra of many new alkaline earth metal containing free radicals (1-7), including $\mathrm{SrOCH}_{3}$. These molecules are made by the reaction of alkaline earth atoms $(\mathrm{Ca}, \mathrm{Sr}$, or Ba ) with alcohols (1, 2), carboxylic acids (1), isocyanic acid (3), cyclopentadiene (4), metal alkyls (5), amines (6), and acetylene (7). The free radical product molecule contains one alkaline earth metal atom and one ligand group.

Low-resolution spectra of alkaline earth monomethoxides were first reported by Wormsbecher and Suenram (8). In these experiments $\mathrm{SrOCH}_{3}$ was produced by the gas-phase reaction of strontium atoms with methyl nitrite, $\mathrm{CH}_{3} \mathrm{ONO}$. A vibrational analysis of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ and $\tilde{B}^{2} A_{1}-\tilde{X}^{2} A_{1}$ transitions was reported.

There are several recent high-resolution analyses of $\operatorname{SrOH}(9,10)$ as well as other alkaline earth monohydroxides, MgOH (11), CaOH (12-14), and BaOH (15). We report here the first high-resolution analysis of a metal monomethoxide. The $0-0$ band of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ transition of $\mathrm{SrOCH}_{3}$ was recorded by laser excitation spectroscopy with narrowband fluorescence detection. A high-resolution analysis is in progress for similar molecules such as $\mathrm{SrNH}_{2}, \mathrm{SrN}_{3}, \mathrm{SrNCO}, \mathrm{CaC}_{2} \mathrm{H}, \mathrm{CaCH}_{3}$, and SrSH by Bernath and co-workers.

There has been some theoretical interest in ${ }^{2} E$ electronic states due to the possibility of Jahn-Teller interactions (16-20). There are only two molecules for which a ${ }^{2} E$ electronic state has previously been studied at high resolution: $\mathrm{CH}_{3} \mathrm{O}$ (21-24) and $\mathrm{FSO}_{3}$ (25). The methoxy radical work is relevant to this study in terms of both the analysis of a ${ }^{2} E$ state and the structural information, which can be transferred to $\mathrm{SrOCH}_{3}$.

The $\mathrm{Sr}-\mathrm{O}-\mathrm{C}$ bond angle in $\mathrm{SrOCH}_{3}$, like the $\mathrm{Sr}-\mathrm{O}-\mathrm{H}$ bond angle, is found to be $180^{\circ}$, and thus $\mathrm{SrOCH}_{3}$ is a prolate symmetric top of $C_{3 v}$ symmetry. The $\tilde{A}^{2} E$ state

[^0]has a large spin-orbit splitting similar to the value of $263 \mathrm{~cm}^{-1}$ for the corresponding $\tilde{A}^{2} \Pi$ state of SrOH . The off-axis hydrogens in $\mathrm{SrOCH}_{3}$ do not perturb the spin-orbit coupling in the $\tilde{A}^{2} E$ state. The $\tilde{A}^{2} E$ state exhibits a strong first-order Coriolis interaction between the orbital angular momentum and the rotational angular momentum. There is no experimental evidence of a Jahn-Teller distortion of $\mathrm{SrOCH}_{3}$ in the $\bar{A}^{2} E$ state.

## METHOD

The production of $\mathrm{SrOCH}_{3}$ in a Broida oven (26) has been described previously (2). Briefly, Sr metal was vaporized from a resistively heated alumina crucible and entrained in a flow of Ar carrier gas ( $\sim 1$ Torr). Methanol is an easier oxidant to use than the methyl nitrite used by Wormsbecher and Suenram (8). However, the methyl nitrite-strontium reaction produces more strontium monomethoxide than the meth-anol-strontium reaction since it is more exothermic. When excited strontium atoms ( ${ }^{3} P_{1} \mathrm{Sr}$ ) are used for the reaction with methanol, a large amount of $\mathrm{SrOCH}_{3}$ is produced, sufficient for the present study.

Two dye laser systems were used. The 5-W all lines output of a Coherent Innova $90-4$ argon ion laser was used to pump a broadband ( $\sim 1 \mathrm{~cm}^{-1}$ ) Coherent 599-01 dye laser operated from 6600 to $7000 \AA$ with DCM dye. Either the 4880 or the $5145 \AA$ output of a Coherent Innova 20 argon ion laser was used to pump a single mode ( $\sim 1$ MHz ) Coherent 699-29 computer-controlled ring dye laser operated near 6760 and $6890 \AA$ with DCM dye and LD 688 dye, respectively. The two output beams from the dye lasers were spatially overlapped and focused into the Broida oven. The output from one of the dye lasers was always tuned to the ${ }^{3} P_{1-1}{ }^{1} S_{0} \mathrm{Sr}$ atomic line at $6892 \AA$. The $\mathrm{SrOCH}_{3}$ laser-induced fluorescence signal was increased by 3 orders of magnitude when excited ${ }^{3} P_{1}$ Sr was used as a reactant. The other dye laser was used to probe for the reaction product, $\mathrm{SrOCH}_{3}$.

For preliminary survey work, the low-resolution laser excitation spectrum was recorded by tuning the ring dye laser to the Sr atomic line and scanning the broadband laser ( $1 \mathrm{~cm}^{-1}$ ) while detecting the laser-induced fluorescence through a red-pass filter (Schott RG 780).

Low-resolution resolved fluorescence spectra were recorded by tuning one laser to the Sr atomic line and the other laser to the $\mathrm{SrOCH}_{3}$ transition. The emission was focused onto the slits of a $0.64-\mathrm{m}$ monochromator and detected with a cooled photomultiplier tube (RCA C31034) using photon counting electronics.

High-resolution laser excitation spectra with narrow band-pass detection were recorded to observe the rotational structure (for example, (27)). For all high-resolution spectra the broadband laser was tuned to the Sr atomic transition.

The $P_{21}$ and $Q_{2}$ bandheads (the splitting of the two heads is too small to be resolved) of the ${ }^{2} E_{3 / 2}{ }^{2} A_{1}$ spin component were recorded by setting the monochromator ( 0.8 $\mathrm{cm}^{-1}$ resolution) in the $P_{2}$ branch and scanning the ring laser through the connecting $P_{21}$ and $Q_{2}$ branches. The notation for a ${ }^{2} \Pi-{ }^{2} \Sigma$ transition, as described by Herzberg (28), will be used for this Hund's case (a) ${ }^{2} E-^{2} A_{1}$ transition. The monochromator acts as a narrowband-pass filter to select the rotational levels connected to the $P_{21}$ and $Q_{2}$ bandheads. Since the different $K$ subbands have nearly the same origin (similar to a parallel transition), the $P_{2}$ rotational lines of different $K$ subbands are badly overlapped.

This proved useful in recording the $P_{21}$ and $Q_{2}$ bandheads. When the monochromator was set in the $P_{2}$ branch, $P_{21}$ and $Q_{2}$ bandheads of 10 to 20 K subbands were recorded in a single scan (Fig. 1).

Individual rotational lines of the ${ }^{2} E_{3 / 2}-^{2} A_{1}$ component were recorded by setting the monochromator on the $P_{21}$ and $Q_{2}$ bandheads of a single subband ( $0.3 \mathrm{~cm}^{-1}$ resolution). In these experiments the monochromator acts as a narrowband-pass filter to select rotational levels belonging to a single subband.

An iodine cell was used to calibrate the wavemeter of the computer-controlled dye laser. The absolute accuracy of our line positions is approximately $\pm 0.005 \mathrm{~cm}^{-1}$.

## RESULTS AND DISCUSSION

## A. Electronic Structure

Low-resolution laser excitation scans were recorded for $\mathrm{SrOCH}_{3}$ in the region 6000 $8200 \AA$. These spectra show vibronic structure belonging to two electronic transitions, $\tilde{B}^{2} A_{1}-\tilde{X}^{2} A_{1}$ and $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$. Figure 2 is a low-resolution laser excitation spectrum of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ transition. The $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ transition is analogous to the $\tilde{A}^{2} \Pi-\tilde{X}^{2} \Sigma^{+}$ transition of the linear SrOH , which is in turn analogous to the $A^{2} \Pi-X^{2} \Sigma^{+}$transition of the strontium monohalides. The bonding in $\mathrm{SrOCH}_{3}$, like SrOH and $\mathrm{Sr} X$, is very ionic, $\mathrm{Sr}^{+}-{ }^{-} \mathrm{OCH}_{3}$, and there is one nonbonding valence electron. For the ground electronic state this electron is in the metal-centered $5 s\left(a_{1}\right)$ orbital, and the electronic transition involves the promotion of this valence electron to the $4 d-5 p(e)$ metal-centered hybrid orbitals.

The $\tilde{A}^{2} E$ state has a spin-orbit splitting of $267.5 \mathrm{~cm}^{-1}$, thus the ${ }^{2} E_{1 / 2}$ and ${ }^{2} E_{3 / 2}$ components are well separated and the $\tilde{A}^{2} E$ state exhibits Hund's case (a) coupling. Hund's case (a) coupling for a ${ }^{2} E$ state has been described in detail by Brown (18). $\dot{\mathbf{L}}$, $\hat{\mathbf{S}}, \hat{\mathbf{R}}$, and $\hat{\mathbf{J}}$ are the orbital angular momentum, spin angular momentum, rotational angular momentum, and the total angular momentum (exclusive of nuclear spin), respectively. The ${ }^{2} E$ state is strongly Hund's case (a), and the projections of $\hat{\mathbf{N}}, \hat{\mathbf{S}}$, and $\hat{\mathbf{J}}$ are quantized along the prolate top axis as $K, \Sigma$, and $P$, respectively, with $P=K$ $+\Sigma$. The projection of $\hat{\mathbf{L}}$ on the top is $\zeta_{e} d$. For a ${ }^{2} E-{ }^{2} A_{1}$ transition the selection rules are $\Delta K= \pm 1, \Delta J=0, \pm 1$.

Fig. 1. Laser excitation spectrum of the strontium monomethoxide $\mathrm{O}_{0}^{0} \tilde{A}^{2} E_{3 / 2}-\tilde{X}^{2} A_{1}$ transition. The blue degraded $Q_{2}$ and $P_{21}$ bandheads form a "head of heads" near $14787 \mathrm{~cm}^{-1}$.

FIG. 2. Low-resolution laser excitation spectrum of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ transition in strontium monomethoxide. The broad feature to the blue is the $\tilde{A}^{2} E_{3 / 2}-\tilde{X}^{2} A_{1}$ transition while the $\tilde{A}^{2} E_{1 / 2}-\tilde{X}^{2} A_{1}$ feature lies between 680 and 690 nm . The sharp feature marked $0-0$ is the $Q_{2}$ and $P_{21}$ bandheads of the $\mathrm{O}_{0}^{0} \tilde{A}^{2} E-\bar{X}^{2} A_{1}$ electronic transition.
$\zeta_{e} d$ corresponds to $\Lambda$ in the linear SrOH case with $\Lambda= \pm 1$ for the corresponding $\tilde{A}^{2} I I$ electronic state. The presence of the off-axis hydrogens can quench the projection of the orbital angular momentum, so usually $\zeta_{e}\left(\mathrm{SrOCH}_{3}\right)<\Lambda(\mathrm{SrOH})$. However, the hydrogens are far from the unpaired electron, which is located on the strontium atom, and very little quenching was expected. The Jahn-Teller effect also quenches the orbital angular momentum through the $d$ portion of the $\zeta_{e} d$ parameter. The small difference in the spin-orbit splitting in SrOH and $\mathrm{SrOCH}_{3}$ is consistent with $\zeta_{e} \sim 1$. For linear SrOH ,

$$
E_{\mathrm{SO}}=A \Lambda \Sigma, \quad \text { where } \quad A=263.5 \mathrm{~cm}^{-1}
$$

while for the symmetric top $\mathrm{SrOCH}_{3}$, only the product $a \zeta_{e} d$ can be determined,

$$
E_{\mathrm{SO}}=a \zeta_{e} d \Sigma, \quad \text { where } \quad a \zeta_{e} d=267.5 \mathrm{~cm}^{-1} .
$$

## B. Vibrational Structure

Since the electronic transitions involve nonbonding orbitals, there is little change in the geometry in the different electronic states of $\mathrm{SrOCH}_{3}$. As a result, the sequence structure is very compact and the Franck-Condon factors are quite diagonal. The bands involving the $\mathrm{Sr}-\mathrm{O}$ stretch have the largest Franck-Condon factors because this mode is associated with the metal atom.
$\mathrm{SrOCH}_{3}$ has 12 normal modes, 4 of $a_{1}$ symmetry and 4 degenerate pairs of $e$ symmetry, for a total of 8 vibrations. These vibrations have the following approximate description: $v_{1}\left(a_{1}\right.$ symmetry) is the $\mathrm{CH}_{3}$ symmetric stretch; $v_{2}\left(a_{1}\right)$ is the $\mathrm{CH}_{3}$ symmetric bend; $\nu_{3}\left(a_{1}\right)$ is the $\mathrm{C}-\mathrm{O}$ stretch; $\nu_{4}\left(a_{1}\right)$ is the $\mathrm{Sr}-\mathrm{O}$ stretch; $\nu_{5}(e)$ is the $\mathrm{CH}_{3}$ asymmetric stretch; $\nu_{6}(e)$ is the $\mathrm{CH}_{3}$ asymmetric bend; $\nu_{7}(e)$ is the $\mathrm{O}-\mathrm{CH}_{3}$ wag; and $\nu_{8}(e)$ is the $\mathrm{Sr}-\mathrm{O}-\mathrm{C}$ bend.

The observed vibrational frequencies are listed in Table I with estimated experimental uncertainties of $\pm 5 \mathrm{~cm}^{-1}$. Several weak ground state vibrational frequencies were detected by exciting the ${ }^{2} E-{ }^{2} A_{1} 0-0$ transition and resolving the fluorescence with a monochromator. The two modes which appear most strongly, $\nu_{4}$ and $\nu_{3}$, have been assigned and reported previously $(2,7)$. The weak feature corresponding to a vibration of $1450 \mathrm{~cm}^{-1}$ is assigned to $\nu_{2}$, the $\mathrm{CH}_{3}$ symmetric bend of $a_{1}$ symmetry. There is one alternative assignment to this feature, that of the $\nu_{6} \mathrm{CH}_{3}$ asymmetric bend of $e$ symmetry. This latter assignment was considered because the two modes in $\mathrm{CH}_{3} \mathrm{OH}$ which correspond to $\nu_{6}$ occur at 1475 and $1455 \mathrm{~cm}^{-1}$. We prefer the $\nu_{2}$ assignment because of symmetry considerations. Within the Born-Oppenheimer approximation for an electric dipole allowed electronic transition, $\Delta v=1$ for vibrations of $a_{1}$ symmetry are allowed while $\Delta v=1$ for an $e$ mode is forbidden (29). The vibronic feature corresponding to a $271 \mathrm{~cm}^{-1}$ vibration was assigned to $2 \nu_{8}$, the $\mathrm{Sr}-\mathrm{O}-\mathrm{C}$ bend. Although $\nu_{8}$ is of $e$ symmetry, transitions involving two quanta in this vibration are allowed (29).

## C. Rotational Structure

$\mathrm{SrOCH}_{3}$ is a prolate symmetric top and we use the $\hat{\mathbf{N}}^{2}$ form of the rotational Hamiltonian developed by Brown (18), extended by Hougen (19), and as explicitly described by Endo et al. (23);

$$
\hat{\mathbf{H}}_{\mathrm{ROT}}=(A-B) \hat{\mathbf{N}}_{z}^{2}+B \hat{\mathbf{N}}^{2},
$$

where $\hat{\mathbf{N}}=\hat{\mathbf{J}}-\hat{\mathbf{S}}$. Centrifugal distortion constants were needed,

$$
\hat{\mathbf{H}}_{\mathrm{CD}}=-D_{N} \hat{\mathbf{N}}^{4}-D_{N K} \hat{\mathbf{N}}^{2} \hat{\mathbf{N}}_{z}^{2}-D_{K} \hat{\mathbf{N}}_{z}^{4}
$$

The first-order electronic Coriolis interaction was also included for the ${ }^{2} E$ state

$$
\hat{\mathbf{H}}_{\mathrm{COR}}=-2 A \hat{\mathbf{N}}_{z} \hat{\mathbf{L}}_{z}+\eta_{e} \hat{\mathbf{N}}^{2} \hat{\mathbf{N}}_{z} \hat{\mathbf{L}}_{z}+\eta_{K} \hat{\mathbf{N}}_{z}^{3} \hat{\mathbf{L}}_{z}
$$

TABLE I
Vibrational Frequencies of $\mathrm{SrOCH}_{3}$

| State | mode | frequency ( $\mathrm{cm}^{-1}$ ) |

a Reference 8.

The energy levels in the $E$ state are split into $(+l)$ and $(-l)$ stacks by this coupling as explained by Herzberg (29). The leading Coriolis term in the Hamiltonian provides a diagonal matrix element of $-2 A \zeta_{t} K$. The effect of this interaction changes the origin of the different $K$ subbands, and when $\zeta_{1}=1$ all subbands have nearly the same origin. Although the ${ }^{2} E-{ }^{2} A_{1}$ transition is formally a perpendicular transition ( $\Delta K= \pm 1$ ), it has the appearance of a parallel transition and thus is very compact (29).

The spin-rotation interaction was included in the ground state Hamiltonian:

$$
\hat{\mathbf{H}}_{\mathrm{SR}}=\epsilon_{a a} \hat{\mathbf{N}}_{z} \hat{\mathbf{S}}_{z}+1 / 4\left(\epsilon_{b b}+\epsilon_{c c}\right)\left(\hat{\mathbf{N}}_{+} \hat{\mathbf{S}}_{-}+\hat{\mathbf{N}}_{-} \hat{\mathbf{S}}_{+}\right)
$$

$\epsilon_{a a}$ was not well determined since this term is significant only for low $J$ lines which could not be detected.

For the excited state, the spin-orbit interaction was included with the term

$$
\hat{\mathbf{H}}_{\mathrm{SO}}=a \hat{\mathbf{L}}_{z} \hat{\mathbf{S}}_{z},
$$

which produces a diagonal matrix element $a \zeta_{l} d \Sigma$. All of the matrix elements of the various terms in the Hamiltonian are explicitly listed by Endo et al. (23). For the ${ }^{2} A_{1}$ state, the matrix elements for $\hat{\mathbf{H}}_{\mathrm{COR}}$ and $\hat{\mathbf{H}}_{\text {SO }}$ are set to zero.

The $0-0$ band of the $\tilde{A}^{2} E_{3 / 2}-\tilde{X}^{2} A_{1}$ transition was recorded at high resolution and analyzed. The $\tilde{A}^{2} E_{1 / 2}-\tilde{X}^{2} A_{1}$ spin component was too compact and the individual rotational lines were unassignable. All the transitions were measured using the monochromator as a narrowband filter to simplify the spectra.

The $\tilde{A}^{2} E_{3 / 2}-\tilde{X}^{2} A_{1}$ transition has six branches per $K$ subband. These are spaced by approximately " $-3 B^{\prime \prime}\left(P_{2}\right), "-B$ " ( $P_{21}$ and $Q_{2}$ ), " $+B$ " ( $Q_{21}$ and $R_{2}$ ), and " $+3 B$ " $\left(R_{21}\right)$ at low $J$, and the $-B$ and $+B$ branches are doubled due to the spin-rotation interaction in the ground state. Spin-rotation doubling was resolved in the $+B$ branch. No sign of $j$-type doubling was observed (analogous to $\Lambda$-type doubling in a $\Pi$ state) because no transitions connecting to $K^{\prime \prime}=1$ in the ${ }^{2} E_{1 / 2}$ component were recorded. Individual rotational lines were recorded in all of the branches except for the $-B$ branch.

Figure 1 is a high-resolution laser excitation spectrum of the $0_{0}^{0}-B$ bandheads recorded through the monochromator. This is a high-resolution scan of the peak marked $0-0$ in the low-resolution ${ }^{2} E_{3 / 2}{ }^{2} A_{1}$ spectrum in Fig. 2. $K^{\prime}$ and $K^{\prime \prime}$ are given above each bandhead. The $-3 B$ and $-B$ branches form blue degraded bandheads. The $-B$ bandheads of different $K$ subbands are very close together due to the first-order Coriolis interaction and actually form a red degraded "head of heads" as shown. The bandhead intensities are not reliable so the ( $K^{\prime}=2, K^{\prime \prime}=3$ ) $-B$ bandhead appears to be the most intense because of the placement of the monochromator filter.

The effect of nuclear spin statistics of the three equivalent hydrogens are clearly shown (Fig. 1) by the $2: 1: 1: 2$ intensity alternation of different $K$ subbands. The intensity of a subband is doubled for $K^{\prime \prime}=0,3,6, \ldots$ The ground state $K^{\prime \prime}$ assignment was straightforward. The $-1 B$ bandheads were recorded by detecting fluorescence in the $-3 B$ branches (Fig. 1). The $K^{\prime}=1-K^{\prime \prime}=0$ subbandhead appears weak (Fig. 2) because for this subband there is no connection between the $-3 B$ and $-B$ branches (like a ${ }^{2} \Pi-^{2} \Sigma^{+}$transition). The $-3 B$ and $-B$ branches terminate on rotational states of different symmetry (parity) in the excited state, separated by $j$ doubling (like $\Lambda$ doubling). For all other subbands, both these symmetry components ( $A_{1}$ and $A_{2}$, or $E$ ) are equally populated by the laser because for $K^{\prime \prime} \neq 0$ the ground state rotational
levels are degenerate ( $A_{1}$ and $A_{2}$ or $E$, see Ref. (29, p. 91)). Thus, the $-3 B$ and $-B$ branches appear in the excitation spectrum. This assignment was also consistent with the nuclear spin statistics for the other $K$ subbands.

There remain two possible assignments for the remaining bands, either $p$ or $r$ type in $K$. The data were fit using both possible excited state $K^{\prime}$ assignments. One choice was eliminated because the ground state $K$-stack origins determined from the fit were physically unreasonable.

The observed $\mathrm{SrOCH}_{3}$ transition wavenumbers which were used in the fit are listed in Table II. A sample spectrum of individual $P$-branch lines is shown in Fig. 3. Lines from six different subbands were recorded $\left[\left(K^{\prime}, K^{\prime \prime}\right)=(10,9),(7,6),(4,3),(0,1),(1\right.$, 0 ), $(2,3)]$. Low $J$ lines could not be observed due to the badly overlapped subbands. Six hundred and twenty lines were fit with 14 parameters with a standard deviation of $0.003 \mathrm{~cm}^{-1}$, close to the estimated measurement error. The molecular constants determined are given in Table III.

The values of the parameters $a$ (spin-orbit), $\zeta_{e}\left(\langle\Lambda| L_{z}|\Lambda\rangle\right)$, and $d$ (Jahn-Teller quenching) are completely correlated so the product $\zeta_{e} d$ was set to the value of 1 in the fit. Since the ${ }^{2} E_{1 / 2}$ spin component was not rotationally analyzed, the value of the spin-orbit constant, $a$, was adjusted to reproduce the location of the $0-{ }^{2} E_{1 / 2}{ }^{2} A_{1}$ subbandheads observed at high resolution. The values of $\zeta_{e}$ and $d$ are expected to be less than or equal to 1 so the value of the spin-orbit constant in $\mathrm{SrOCH}_{3}(267.53$ $\mathrm{cm}^{-1}$ ) is slightly larger than the corresponding SrOH value of $263.52 \mathrm{~cm}^{-1}$.

The constants $A^{\prime}, a$, and $\zeta_{t}$ are also correlated and cannot be simultaneously determined. For the final fit $A^{\prime \prime}$ was set to $5.1851 \mathrm{~cm}^{-1}$, the value Endo et al. (23) observed for $\mathrm{CH}_{3} \mathrm{O}$. The parameter $\zeta_{t}$ was badly correlated with other parameters so it was fixed to the value of 1 .

There is no experimental evidence for a Jahn-Teller effect in the $\tilde{A}^{2} E$ state of $\mathrm{SrOCH}_{3}$. The vibrational structure for the Jahn-Teller active mode $\nu_{8}$, the $\mathrm{Sr}-\mathrm{O}-\mathrm{C}$ bend, displayed the selection rule $\Delta v_{8}= \pm 2$ not $\Delta v_{8}= \pm 1$. The molecular parameters derived from the rotational structure have reasonable values consistent with the assumptions $\zeta_{e} d$ and $\zeta_{t}=1$.

The $\tilde{A}^{2} E$ state in $\mathrm{SrOCH}_{3}$ is quite different from the $\tilde{X}^{2} E$ state of $\mathrm{OCH}_{3}$. The electronic structure of the $\tilde{A}^{2} E$ state of $\mathrm{SrOCH}_{3}$ can be viewed as a nonbonding, unpaired electron in a $p \pi-d \pi$ orbital polarized away from a $\mathrm{Sr}^{2+}$ core. The large $\mathrm{Sr}^{2+}$ core separates the closed-shell ${ }^{-} \mathrm{OCH}_{3}$ ligand from the unpaired electron. The three off-axis hydrogens are thus far away from the unpaired electron. The unpaired electron sees a locally linear environment resulting in a spin-orbit coupling constant similar to SrOH and an unobservably small Jahn-Teller effect. The unpaired electron does not communicate with the three hydrogen atoms.

The rotational structure of $\mathrm{SrOCH}_{3}$ is consistent with a $C_{3 v}$ geometry for both $\tilde{A}^{2} E$ and $\tilde{X}^{2} A_{1}$ electronic states. The covalent $\mathrm{CH}_{3} \mathrm{OH}$ molecule has $C_{s}$ symmetry, but if the H atom bonding to the oxygen is replaced by a more electronegative atom such as Li or Na , ab initio calculations predict a $C_{3 v}$ structure ( 30,31 ).

The electronic charge distribution is $M^{+}-{ }^{-} \mathrm{OCH}_{3}$ with some delocalization of the negative charge over the $\mathrm{CH}_{3}$ group. Calculations on $\mathrm{CH}_{3} \mathrm{O}^{-}$predict (32) that the $\mathrm{O}^{-}$ donates electrons into an unoccupied $\pi^{*}$ orbital on the carbon atom. This interaction shortens the $\mathrm{O}-\mathrm{C}$ bond, lengthens the $\mathrm{C}-\mathrm{H}$ bonds, and decreases the $\mathrm{H}-\mathrm{C}-\mathrm{H}$ angle.

## 14777

Fig. 3. High-resolution laser excitation spectrum of the ${ }^{\prime} P_{2}\left(J, K^{\prime \prime}=3\right)$ branch of the $\mathrm{O}_{0}^{0}$ band. The monochromator, set on the connecting $Q_{2}$ and $P_{21}$ bandheads, acts as a narrowband-pass filter to select the lines from a single branch of a single subband.

As a result of the changes in bond order, the O-C vibrational frequency increases while the $\mathrm{C}-\mathrm{H}$ frequencies decrease. These changes are manifestations of an effect called "anionic hyperconjugation" (33, 34).

TABLE III
The Molecular Constants for the 0-0 Band of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ Transition of $\mathrm{SrOCH}_{3}\left(\mathrm{~cm}^{-1}\right)$

| $A^{\prime \prime}$ | $5.18511^{\text {a }}$ |
| :---: | :---: |
| $B^{\prime \prime}$ | $8.39706(45) \times 10^{-2} \mathrm{~b}$ |
| $\mathrm{D}_{\mathrm{K}}{ }^{\prime \prime}$ | 4.151(29) $\times 10^{-3}$ |
| $\mathrm{D}_{\mathrm{N}}{ }^{\prime \prime}$ | $1.07(10) \times 10^{-8}$ |
| $\mathrm{D}_{\mathrm{NK}}{ }^{\prime \prime}$ | $1.431(59) \times 10^{-6}$ |
| ${ }^{6}$ aa" | -1.78(38) $\times 10^{-3}$ |
| ${ }^{\epsilon} \mathrm{bb}^{+\epsilon} \mathrm{cc}{ }^{\prime \prime}$ | $1.586(28) \times 10^{-3}$ |
| To' | 14658.8721(9) |
| $\mathrm{a}_{\text {SO }}{ }^{\prime}$ | 267.53(30) ${ }^{\text {c }}$ |
| $\zeta e^{d^{\prime}}$ | $1.0{ }^{\text {d }}$ |
| $5 t^{\prime}$ | $1.0{ }^{\text {d }}$ |
| $A^{\prime}$ | 5.15244(16) |
| B' | 8.50396(45) $\times 10^{-2}$ |
| $\mathrm{D}_{\mathrm{K}}{ }^{\prime}$ | 4.155(28) $\times 10^{-3}$ |
| $\mathrm{D}_{\mathrm{N}}{ }^{\prime}$ | $1.08(10) \times 10^{-8}$ |
| $\mathrm{D}_{\mathrm{NK}}{ }^{\prime}$ | $1.261(62) \times 10^{-6}$ |
| $\eta{ }^{\prime}$ | $2.95(17) \times 10^{-6}$ |
| ${ }^{\prime}{ }_{K}{ }^{\prime}$ | $1.676(10) \times 10^{-2}$ |

[^1]There are four structural parameters for $\mathrm{SrOCH}_{3}$, so some assumptions are required in order to extract a geometry from a single $B_{0}$ value. The photoelectron spectrum of $\mathrm{CH}_{3} \mathrm{O}^{-}$recorded by Engelking et al. (35) suggests that the $\mathrm{C}-\mathrm{O}$ bondlength is similar for $\mathrm{CH}_{3} \mathrm{O}^{-}$and $\mathrm{CH}_{3} \mathrm{O}$. On this basis we choose $r_{\mathrm{CO}}=1.376 \AA$ from the microwave work of Endo et al. (23) on $\mathrm{CH}_{3} \mathrm{O}$. If we choose a CH bondlength of $1.0937 \AA$ (assumed in Ref. (23)) and an H-C-H bond angle of $110.66^{\circ}$ (derived in Ref. (23)) to match the $\mathrm{OCH}_{3}$ values, then $r_{0}=2.123 \AA$ for $\mathrm{Sr}-\mathrm{O}$ in the $\tilde{X}^{2} A_{1}$ state. In the excited $\tilde{A}^{2} E$ state $r_{0}=2.104 \AA$ for $\mathrm{Sr}-\mathrm{O}$ and the $\mathrm{H}-\mathrm{C}-\mathrm{H}$ angle is $107.99^{\circ}$. This angle is derived from the $A^{\prime}$ value with $\zeta_{t}=1$ and the CH bondlength equal to $1.0937 \AA$. The $\mathrm{Sr}-\mathrm{O}$ bondlength is thus $0.02 \AA$ shorter in the excited state and $\mathrm{H}-\mathrm{C}-\mathrm{H} 2.7^{\circ}$ smaller than in the ground state.

Consideration of the effects of anionic hyperconjugation will change these conclusions slightly but we are unable to find a suitable state-of-the-art ab initio calculation (large basis set and large scale configuration interaction). The $\mathrm{C}-\mathrm{O}$ bondlength ranges from 1.33 to $1.40 \AA$ in $\mathrm{CH}_{3} \mathrm{O}^{-}$crystal structures ( 36,37 ). If the CH bondlength in $\mathrm{SrOCH}_{3}$ is increased to $1.12 \AA$ and the $\mathrm{H}-\mathrm{C}-\mathrm{H}$ angle decreased to $103^{\circ}$, then the $\mathrm{Sr}-$ O bondlength is $2.103 \AA$ in the $\tilde{X}^{2} A_{1}$ state. These $\mathrm{Sr}-\mathrm{O}$ bondlengths compare favorably with the $\mathrm{Sr}-\mathrm{O}$ bondlength of $2.111 \AA$ derived for the SrOH molecule. (9)

## CONCLUSION

The rotational analysis of the $0-0$ band of the $\tilde{A}^{2} E-\tilde{X}^{2} A_{1}$ transition of $\mathrm{SrOCH}_{3}$ was carried out by laser excitation spectroscopy with narrowband fluorescence detection. This work is the first high-resolution analysis of a metal alkoxide molecule. The $\tilde{A}^{2} E$ state shows no sign of a Jahn-Teller effect. The $\mathrm{Sr}-\mathrm{O}$ bondlength was found to be $2.12 \AA$, similar to the value in the SrOH molecule.
