# The $\tilde{B}^{2} \Sigma^{+}-\tilde{X}^{2} \Sigma^{+}$Transition of CaOD 

R. A. Hailey, C. N. Jarman, W. T. M. L. Fernando, and P. F. Bernath ${ }^{1}$<br>Department of Chemistry, University of Arizona, Tucson, Arizona 85721

#### Abstract

The $\dot{B}^{2} \Sigma^{+}-\check{X}^{2} \Sigma^{+}$transition of CaOD near $5550 \AA$ was studied using dye laser excitation spectroscopy. The $000-000$ band was rotationally analyzed and $r_{0}$ structures were established for both states. For the $\tilde{B}^{2} \Sigma^{+}$state the following bond lengths were found: $r_{\mathrm{Ca}-\mathrm{O}}=1.9697 \AA$ and $r_{\mathrm{O}-\mathrm{H}}=0.9179 \AA$, while for the $\grave{X}^{2} \Sigma^{+}$state $r_{\mathrm{Ca}-\mathrm{O}}=1.9849 \AA$ and $r_{\mathrm{O}-\mathrm{H}}=0.9207 \AA$. . 1991 Academic Press, Inc.

## INTRODUCTION

The spectra of CaOH are well known because when calcium salts are added to flames, the reddish and greenish emission of CaOH is observed ( 1,2 ). The red emission near $6220-6270 \AA$ belongs to the $\hat{A}^{2} \Pi-\tilde{X}^{2} \Sigma^{+}$system, while the green emission near 5550 Å corresponds to the $\tilde{B}^{2} \Sigma^{+}-\tilde{X}^{2} \Sigma^{+}$transition (2). Hilborn et al. (3) rotationally analyzed the 000-000 band of the $\tilde{A}^{2} \Pi-\dot{X}^{2} \Sigma^{+}$transition for both CaOH and CaOD. Bernath and Kinsey-Nielsen (4) analyzed the $\dot{B}^{2} \Sigma^{+}-\dot{X}^{2} \Sigma^{+}$transition of CaOH , while Bernath and Brazier (5) measured some additional $\hat{A}^{2} \Pi-\hat{X}^{2} \Sigma^{+}$lines and fitted the $\hat{A}_{-}$ $\tilde{X}$ and $\tilde{B}-\tilde{X}$ data together.

The initial goal of our work was to investigate the highly excited electronic states of CaOH using the technique of optical-optical double resonance. Many new vibronic states were found during the course of our research, but it was necessary to differentiate the origin bands from vibrationally excited bands by using isotopic substitution. While the rotational analysis for the $000-000$ band of the $\tilde{B}^{2} \Sigma^{+}-\tilde{X}^{2} \Sigma^{+}$transition of CaOH is complete (4), the corresponding CaOD transition had not been analyzed. Consequently it was necessary to record the high-resolution spectrum of the green system of CaOD to aid in our optical-optical double resonance assignments. This paper contains the rotational analysis of the $000-000$ band of $\tilde{B}^{2} \Sigma^{+}-\tilde{X}^{2} \Sigma^{+}$transition of CaOD, as well as $r_{0}$ structures for both states.

## EXPERIMENTAL DETAILS

The CaOD was produced in a Broida-type oven (6) by the reaction of Ca metal vapor and $\mathrm{D}_{2} \mathrm{O}_{2}$. It was found that the $\mathrm{D}_{2} \mathrm{O}_{2}$ produced more CaOD than $\mathrm{D}_{2} \mathrm{O}$ in the reaction with ground state ( ${ }^{1} S_{0}$ ) Ca vapor. The calcium was vaporized in a resistively heated alumina crucible and a flow of argon carried the Ca atoms from the crucible to the reaction region. In order to get sufficient $\mathrm{D}_{2} \mathrm{O}_{2}$ partial pressure inside of the oven, argon was bubbled through the oxidant. The pumping speed and the flow rate

Fig. 1. High-resolution CaOD spectrum. This is a section of the laser excitation spectrum of the $P_{1}$ branch of the $000-000$ band of the $\dot{B}^{2} \Sigma^{+}-\dot{X}^{2} \Sigma^{+}$transition. The $P_{1}$ branch forms a head at $17991.828 \mathrm{~cm}^{-1}$.
were adjusted to optimize the signal. The total pressure in the oven was $\sim 7$ Torr ( mostly argon and a few mTorr $\mathrm{D}_{2} \mathrm{O}_{2}$ ).
$\mathrm{D}_{2} \mathrm{O}_{2}$ was made by the deuteration of $30 \% \mathrm{H}_{2} \mathrm{O}_{2}$. First the excess water was pumped off and then $99.9 \% \mathrm{D}_{2} \mathrm{O}$ was added to the $\mathrm{H}_{2} \mathrm{O}_{2}$. After deuteration, the mixture was concentrated by pumping off the excess water. This procedure was repeated several times.

The laser used in this experiment was a single-frequency Coherent 699-29 ring dye laser pumped by a Coherent Innova 20 argon ion laser ( 8 W ). The dye laser was operated with Rhodamine 110 dye. The laser beam was focused horizontally into the flame. Spectra were obtained by scanning the computer controlled ring dye laser while detecting the total fluorescence with a photomultiplier tube. The wavemeter of the ring dye laser was calibrated by simultaneously recording an excitation spectrum iodine vapor (7). The line positions have been corrected by the subtraction of $0.0056 \mathrm{~cm}^{-1}$ (8). The measured CaOD lines are listed in Table I. The estimated accuracy of the line positions is $\pm 0.004 \mathrm{~cm}^{-1}$.

RESULTS AND DISCUSSION
A portion of the laser excitation spectrum of the $\tilde{B}^{2} \Sigma^{+}-\dot{X}^{2} \Sigma^{+}$transition of CaOD near the $P_{1}$ head of the $000-000$ band is shown in Fig. 1. Each ${ }^{2} \Sigma^{+}$state has two spin components $\left[F_{1}(e)\right.$ and $F_{2}(f)$ ] and therefore the ${ }^{2} \Sigma^{+}-^{2} \Sigma^{+}$transition consists of four branches, $P_{1}, P_{2}, R_{1}$, and $R_{2}$ at high $N(9)$. The $P$ branches form heads at 17991.828 and $17994.554 \mathrm{~cm}^{1}$, for the $F_{1}$ and $F_{2}$ spin components, respectively. Because the $\tilde{X}$ and $\tilde{B}$ state potential curves are very similar the band heads occur at very high $N$ ( $N=70$ for $P_{1}$ and $N=66$ for $P_{2}$ ). The $R$ branch region of the spectrum contains many vibrational sequence bands as well as the $R_{1}$ and $R_{2}$ branches of the 000-000 band. In order to analyze these sequence bands the technique of laser excitation spectroscopy with filtered fluorescence detection must be used.

The rotational lines of the $P_{1}$ and $P_{2}$ branches were easy to pick out, but because of the many interfering lines present in the $R$ branch region it was difficult to pick

TABLE II

| Parameter ${ }^{\text {a }}$ |  | $\mathrm{B}^{-2}{ }^{+}$ |
| :---: | :---: | :---: |
| T0 | 0.9 | $18013.894(4)$ |
| $\mathrm{B}_{3}$ | 0.303004(83) | 9. $307488(85)$ |
| $\mathrm{D}_{0}$ | 3.016 (25) $\times 10^{\circ}$ | 3.156(26) $\times 10^{-}$ |
| $y_{0}$ | $0.001006^{6}$ | -0.039536(13) |

[^2]out the $R$-branch rotational lines. The rotational assignments were made by first predicting the spectrum using an estimated band origin and molecular constants. The initial estimates were made using the previous work for CaOD (3) and CaOH (5). Then the band origin was changed until the positions of the $P$ heads, as well as the pattern of the $R$ rotational lines in the predicted spectrum, matched the actual line positions.

The lines were fit to the ${ }^{2} \Sigma$ energy level expression using a nonlinear least-squares program. The Hund's case (a) matrix elements of the standard ${ }^{2} \Sigma$ Hamiltonian (10) used in this analysis are listed in the paper by Douay et al. (11). Only $\gamma^{\prime}-\gamma^{\prime \prime}$ is well determined, therefore for the final fit $\gamma^{\prime \prime}$ was fixed to the value obtained using the isotopic relationship

$$
\begin{equation*}
\gamma_{\mathrm{CaOD}}=\gamma_{\mathrm{CaOH}} \frac{B_{\mathrm{CaOD}}}{B_{\mathrm{CaOH}}} . \tag{1}
\end{equation*}
$$

$B_{\mathrm{CaOH}}$ and $\gamma_{\mathrm{CaOH}}$ were taken from the results of Bernath and Brazier (5). The molecular constants from the final fit are presented in Table II.

The accuracy of Eq. (1) can be checked by substituting the $\gamma_{\text {CaOD }}^{\prime}$ from this work into Eq. (1), and predicting the $\gamma_{\mathrm{CaOH}}^{\prime}$ value ( $-0.043640 \mathrm{~cm}^{-1}$ ). This value is identical, within experimental error, to the result from Bernath and Brazier ( -0.0436 15(46)

$\mathrm{cm}^{-1}$ ) (5). The ground state constants are in reasonable agreement with those of Hilborn et al. (3).

CaOH and CaOD are linear. Using the relationship between the moment of inertia and the bond lengths of a linear molecule

$$
\begin{equation*}
I=\frac{1}{M}\left(m_{1} m_{2} r_{12}^{2}+m_{1} m_{3} r_{13}^{2}+m_{2} m_{3} r_{23}^{2}\right) \tag{2}
\end{equation*}
$$

the $r_{0}$ structures for CaOH in both the $\dot{B}^{2} \Sigma^{+}$and $\tilde{X}^{2} \Sigma^{+}$states were determined. The moments of inertia for CaOD are calculated from the $B$ values of Table II, while the corresponding data for CaOH were taken from the work of Bernath and Brazier (5). The results are presented in Table III. The bond lengths of the $\tilde{B}^{2} \Sigma^{+}$state are shorter than in the $\tilde{X}^{2} \Sigma^{+}$state which suggests that the nonbonding valence electron has slight antibonding character in the ground state.

For the $\tilde{X}^{2} \Sigma^{+}$state the Ca-O bond length ( $1.985 \check{A}$ ) agrees with the value of Hilborn et al. (3), but the ground state O-H bond length $(0.921 \AA)$ is different than their value $(0.901 \AA)$. This difference reflects the slightly different $B$ values used in our analysis, and we note that $r_{0}$ structures for hydrogen atom positions are notoriously unreliable. However, the O-H bond length obtained in this work compares quite well with the $\mathrm{O}-\mathrm{H}$ bond lengths found in the other alkaline earth monohydroxides. The known bond lengths of the ground states of the alkaline earth hydroxides are provided in Table IV for comparison purposes.
