#### Abstract

The emission spectrum of ZrCl has been observed in the $1800-12000 \mathrm{~cm}^{-1}$ region using a Fourier transform spectrometer. The molecules were excited in a microwave discharge of a mixture of helium and a trace of $\mathrm{ZrCl}_{4}$ vapor. In addition to the $C^{4} \Delta-X^{4} \Phi$ transition reported previously, numerous new bands observed in the near infrared have been classified into two electronic transitions, $[7.3]^{2} \Delta-a^{2} \Phi$ and $[9.4]^{2} \Phi-a^{2} \Phi$. Five new bands observed in the $6700-7400 \mathrm{~cm}^{-1}$ region have been assigned as ${ }^{2} \Delta_{3 / 2}-^{2} \Phi_{5 / 2}$ and ${ }^{2} \Delta_{5 / 2}{ }^{2} \Phi_{7 / 2}$ subbands of a new electronic transition, [7.3] ${ }^{2} \Delta-a^{2} \Phi$. The two subbands of the $[9.4]^{2} \Phi-a^{2} \Phi$ transition were previously observed by G. Phillips, S. P. Davis, and D. C. Galehouse [Astrophys. J. Suppl. 43, 417-434 (1980)], who tentatively labeled them as ${ }^{2} \Pi_{1 / 2}-{ }^{2} \Pi_{1 / 2}$ and ${ }^{2} \Pi_{3 / 2}-{ }^{2} \Pi_{3 / 2}$ subbands. A number of new bands involving higher vibrational levels have been identified for these two subbands. A rotational analysis of a number of bands of both transitions has been obtained and spectroscopic constants have been determined. Global perturbations have been observed in both spin components of the $a^{2} \Phi$ state. The assignment of the observed electronic states has been discussed in light of recent theoretical calculations. © 1999 Academic Press

## INTRODUCTION

Although the electronic spectra of ZrCl have been known for several decades (1), the identity of the ground state has always been in question. $\mathrm{A}^{4} \Sigma^{-}$ground state was suggested on the basis of a vibrational analysis of ZrCl bands observed in the $400-415 \mathrm{~nm}$ region by radio frequency excitation of $\mathrm{ZrCl}_{4}$ vapor (1). These bands were reinvestigated by Jordan et al. (2) using a corona-excited supersonic jet source. They classified these bands into four subbands of a ${ }^{4} \Pi^{-} \Sigma^{-}$transition with the ${ }^{4} \Sigma^{-}$state assigned as the ground state, although no rotational analysis was carried out. The $400-415 \mathrm{~nm}$ bands probably belongs to a ${ }^{4} \Gamma-{ }^{4} \Phi$ system, by analogy with recent work on TiCl (3). Phillips et al. (4) have observed another transition of ZrCl in the near infrared, which was assigned as a $\Delta \Omega=0$ doublet-doublet transition. Again no conclusion was drawn about the nature of the ground state, although a ${ }^{2} \Pi$ or ${ }^{2} \Delta$ assignment was proposed for the lower and upper excited states of this transition.

Recently we have investigated the electronic spectra of ZrCl in the $3000-10000 \mathrm{~cm}^{-1}$ region. We have observed a new transition of ZrCl in the $3600-4400 \mathrm{~cm}^{-1}$ region which has been assigned as the $\mathrm{C}^{4} \Delta-X^{4} \Phi$ transition (5). The ${ }^{4} \Phi$ ground state assignment for ZrCl is consistent with our recent findings for TiCl (6) and $\mathrm{TiF}(7)$ and is also consistent with recent $a b$ initio results for TiF (8). A high-level ab initio study of TiF has been carried out by Harrison (8), who calculated the spectroscopic properties of a number of doublet and quartet states. This work predicts a ${ }^{4} \Phi$ state as the ground state consistent with the results of $\mathrm{TiH}(9-11)$. According to this calculation,
the ground state of TiF is followed by a close-lying ${ }^{4} \Sigma^{-}$state about 0.1 eV above the $X^{4} \Phi$ state and the lowest doublet state is a ${ }^{2} \Phi$ state which lies about 0.65 eV above the ground ${ }^{4} \Phi$ state. Similar electronic structure is also expected for the TiCl and ZrCl molecules. The $a b$ initio calculations of Boldyrev and Simons (12) support the ${ }^{4} \Phi$ assignment of the ground state for both TiF and TiCl .

Recently Focsa et al. have calculated the spectroscopic properties of the low-lying electronic states of TiCl (13) and ZrCl (14) using ligand field theory. These calculations have also confirmed our assignment of the ${ }^{4} \Phi$ ground state and have predicted the location of other low-lying doublet and quartet states. $\mathrm{A}^{2} \Phi$ state has been predicted to be the lowest in the doublet manifold of states. Recently we have observed a dou-blet-doublet transition of TiCl in the near infrared which has been labeled as the $[12.8]^{2} \Phi-a^{2} \Phi$ transition (15). The assignment of the lower state as $a^{2} \Phi$ is also supported by the calculations of Focsa et al. (13) for TiCl , but we cannot rule out a $[12.8]^{2} \Delta-a^{2} \Delta$ assignment. The infrared transition of ZrCl , reported initially by Phillips et al. (4) is analogous to the $[12.8]^{2} \Phi-a^{2} \Phi$ transition of TiCl (15). This transition has been renamed as the $[9.4]^{2} \Phi-a^{2} \Phi$ transition in the present paper.

In our recent work on the near-infrared spectra of ZrCl (5) we noted that several weaker bands remained unassigned. In this paper we report on the analysis of numerous such bands in the $6700-12000 \mathrm{~cm}^{-1}$ region. Several new bands observed in the 7700-12 $000 \mathrm{~cm}^{-1}$ region have been identified as higher vibrational bands of the transition initially analyzed by Phillips et al. (4). In addition, another low-lying transition, $[7.3]^{2} \Delta-$ $a^{2} \Phi$, with a common lower state has been observed in the
$6700-7400 \mathrm{~cm}^{-1}$ region. The rotational analysis of these two transitions will be reported in this paper and the nature of the observed electronic states will be discussed in light of the available theoretical calculations.

## EXPERIMENTAL DETAILS

The experimental conditions and methods of observation of the ZrCl bands have been provided in detail in our previous paper (5). In summary, the ZrCl molecules were excited in a microwave discharge through a flowing mixture of about 3 Torr of helium and a trace of $\mathrm{ZrCl}_{4}$ vapor. The spectra were recorded using the $1-\mathrm{m}$ Fourier transform spectrometer of the National Solar Observatory at Kitt Peak. The spectra in the $1800-9000 \mathrm{~cm}^{-1}$ region were recorded using liquid-nitrogencooled InSb detectors and Si filters. A total of 10 scans were co-added in about 60 min of integration at a resolution of 0.02 $\mathrm{cm}^{-1}$.

The spectral line positions were measured using a data reduction program called PC-DECOMP developed by J. Brault. The peak positions were determined by fitting a Voigt lineshape function to each line. The ZrCl bands in the $9000-$ $12000 \mathrm{~cm}^{-1}$ region were measured from the spectra used by Phillips et al. (4) in their previous study of this molecule. Since no molecular or atomic lines suitable for calibration were present in the 9000-12 $000 \mathrm{~cm}^{-1}$ region, the sharp atomic lines common to both the spectra were first calibrated using the measurements of the vibration-rotation lines of the $1-0$ band of $\mathrm{HCl}(16)$ which appear in our spectra. This calibration was then transferred to the spectra in the $9000-12000 \mathrm{~cm}^{-1}$ region. All of the bands observed in the $9000-12000 \mathrm{~cm}^{-1}$ region including those reported in the paper of Phillips et al. (4) were remeasured. There is excellent agreement between the present measurements and those of Phillips et al. (4). A maximum deviation of $\pm 0.002 \mathrm{~cm}^{-1}$ has been observed between the two sets of measurements. The molecular lines appear with a width of $0.035 \mathrm{~cm}^{-1}$ and a maximum signal-to-noise ratio of about 13:1. The line positions are expected to be accurate to about $\pm 0.003 \mathrm{~cm}^{-1}$. However, because there is considerable overlapping and blending caused by the presence of different subbands in the same region, the error in the measurement of blended and weak lines is expected to be somewhat higher.

## OBSERVATIONS AND ANALYSIS

In addition to the $\mathrm{C}^{4} \Delta-X^{4} \Phi$ transition of ZrCl reported previously, numerous additional bands have been observed in our spectra in the $6700-12000 \mathrm{~cm}^{-1}$ region. Most of these bands have been assigned as involving doublet-doublet transitions. The electronic assignment of these transitions has been made with the help of recent theoretical predictions for TiCl (13) and ZrCl (14). A schematic energy level diagram of the observed doublet-doublet transitions is provided in Fig. 1.

A number of bands observed in the $8000-12000 \mathrm{~cm}^{-1}$

FIG. 1. A schematic energy level diagram of the observed doublet states of ZrCl .
region have been assigned previously by Phillips et al. (4) into two doublet-doublet subbands with the $0-0$ origins near 9133 and $9605 \mathrm{~cm}^{-1}$, respectively. These two subbands were labeled as ${ }^{2} \Pi_{1 / 2}-{ }^{2} \Pi_{1 / 2}$ and ${ }^{2} \Pi_{3 / 2-}{ }^{-} \Pi_{3 / 2}$ transitions (4). In the present paper we have renamed this transition as $[9.4]^{2} \Phi-a^{2} \Phi$ based on a recent theoretical calculation (14) and experimental observations on the isovalent TiCl in the $10000-13000 \mathrm{~cm}^{-1}$ region (15). The number quoted in square brackets is the average of the $T_{00}$ values of the two subbands in units of 1000 $\mathrm{cm}^{-1}$. The two $\Delta \Omega=0$ transitions of ZrCl (4) are thus the $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ and $[9.4]^{2} \Phi_{7 / 2}-a^{2} \Phi_{7 / 2}$ subbands.

Several of the bands in the $7000-8700 \mathrm{~cm}^{-1}$ region were assigned as higher vibrational bands in the $\Delta \mathrm{v}=-2$ and -3 sequences of the $[9.4]^{2} \Phi-a^{2} \Phi$ transition. In addition, five new bands observed in the $6700-7400 \mathrm{~cm}^{-1}$ region have been assigned as two subbands of a new doublet-doublet transition with $\Delta \Omega= \pm 1$. These bands are much weaker in intensity than the bands of Phillips et al. (4) but involve the same lower state. This transition has been labeled as $[7.3]^{2} \Delta-a^{2} \Phi$ in the present paper.

## (a) The $[9.4]^{2} \Phi-a^{2} \Phi$ Transition

Phillips et al. (4) assigned three bands located near 8721, 9133 , and $9487 \mathrm{~cm}^{-1}$ as the $0-1,0-0$, and $1-0$ bands, respectively, of the ${ }^{2} \Pi_{1 / 2}{ }^{-} \Pi_{1 / 2}$ subband [present notation, [9.4] ${ }^{2} \Phi_{7 / 2}{ }^{-}$ $\left.a^{2} \Phi_{72}\right]$ and seven ZrCl bands near 8730, 8785, 9195, 9605, 9957, 10246 , and $10309 \mathrm{~cm}^{-1}$ as the $1-3,0-2,0-1,0-0$, $1-0,3-1$, and $2-0$ bands, respectively, of the ${ }^{2} \Pi_{3 / 2}{ }^{2} \Pi_{3 / 2}$ subband [present notation, $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ ]. In the present work we have extended the previous observations to include bands involving higher vibrational levels of the lower and excited states. In particular the new bands observed near 9838, 9776, $8315,8257,7855$ and $7806 \mathrm{~cm}^{-1}$ have been assigned as

FIG. 2. An expanded portion of the $0-2$ band of the $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ subband of ZrCl .
$2-0,3-1,0-2,1-3,1-4$ and $2-5$ bands of the $[9.4]^{2} \Phi_{7 / 2}-a^{2} \Phi_{7 / 2}$ subband and the bands observed near 9137, 8727, 8375, 8323 $\mathrm{cm}^{-1}$ have been assigned as the $1-2,1-3,0-3$ and $1-4$ bands of the $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ subband. All of these new bands have been rotationally analyzed. The rotational structure of each subband consists of two branches: one $R$ and one $P$, along with the isotopic companions involving ${ }^{37} \mathrm{Cl}$ and various isotopes of Zr . The rotational structure of the $0-2$ band of the $[9.4]^{2} \Phi_{5 / 2}-$ $a^{2} \Phi_{5 / 2}$ subband is provided in Fig. 2, where only the lines of the most abundant ${ }^{90} \mathrm{Zr}^{35} \mathrm{Cl}$ isotopomer have been marked. The unmarked lines are due to the less abundant isotopomers involving ${ }^{91} \mathrm{Zr}$ (11.2\%), ${ }^{92} \mathrm{Zr}$ (17.2\%), ${ }^{94} \mathrm{Zr}$ (17.4\%), ${ }^{96} \mathrm{Zr}$ (2.7\%), or ${ }^{37} \mathrm{Cl}(24.2 \%)$ isotopes. No $\Omega$-doubling was observed in any of the bands. The rotational constants for only the most abundant ${ }^{90} \mathrm{Z}{ }^{35} \mathrm{Cl}$ isotopomer have been obtained. The relative size of the $B_{\text {eff }}$ values was used to distinguish between the ${ }^{2} \Phi_{72}$ and
${ }^{2} \Phi_{5 / 2}$ spin components because first lines were not detected. The observed states have been assigned as regular as suggested by the calculations of Focsa et al. $(13,14)$ [Fig. 1].

## (b) The $[7.3]^{2} \Delta-a^{2} \Phi$ transition

On the lower wavenumber side of the $[9.4]^{2} \Phi-a^{2} \Phi$ transition, several weaker bands with $R$ heads near 6835, 6940, 7246, 7351 , and $7714 \mathrm{~cm}^{-1}$ could not be accommodated into the Deslandres table of the two subbands described previously. A careful inspection of the rotational structure of these bands indicates that they have strong $Q$ branches and, therefore, involve $\Delta \Omega= \pm 1$ transitions. A rotational analysis of the bands near 6835 and $7246 \mathrm{~cm}^{-1}$ indicates that they are the $0-1$ and $0-0$ bands of a new subband with the $a^{2} \Phi_{7 / 2}$ spin component as its lower state, while the bands near 6940, 7351, and

$7714 \mathrm{~cm}^{-1}$ are the $0-1,0-0$, and $1-0$ bands of another new subband with the $a^{2} \Phi_{5 / 2}$ spin component as its lower state. These bands are much weaker in intensity than the bands described previously. A compressed portion of the spectrum showing the $0-1$ bands of the two subbands is provided in Fig. 3. The present observation suggests that the excited state of this transition is either a ${ }^{2} \Delta$ or a ${ }^{2} \Gamma$ state. It is difficult to decide between the ${ }^{2} \Delta$ or the ${ }^{2} \Gamma$ assignment because the intensity of the $R$ and $P$ branches is similar and the $Q$ branch is most intense. No $\Omega$ doubling has been observed in any of the bands. In the present paper we have preferred the ${ }^{2} \Delta$ assignment on the basis of the theoretical predictions of Focsa et al. for TiCl (13) and ZrCl (14).

The rotational assignments in the different bands were made by comparing combination differences for the common vibrational levels. The observed electronic states probably belong to Hund's case (a) coupling but the subbands were not fitted together. Rather than fitting all of the lines together with assumed spin-orbit constants, we decided to use the following
simple empirical term energy expression for each spin component:

$$
\begin{align*}
F_{v}(J)=T_{v}+B_{v} J & (J+1) \\
& -D_{v}[J(J+1)]^{2}+H_{v}[(J+1)]^{3} \tag{1}
\end{align*}
$$

Initially a band-by-band fit was obtained for each subband. This fit provided similar constants for common vibrational levels, confirming the vibrational assignments. In the final fit, the lines of all of the vibrational bands of each subband with a common lower state were combined and fitted simultaneously. The observed line positions for the new bands of the $[9.4]^{2} \Phi-$ $a^{2} \Phi$ transition are provided in Table 1 while the line positions for the new $[7.3]^{2} \Delta-a^{2} \Phi$ transition are provided in Table 2. The rotational constants were determined by weighting the individual lines according to signal-to-noise ratio and extent of blending. Badly blended lines were heavily deweighted. The

Note. Values in parentheses are one standard deviation in the last digits and "a" and "b" refer to the undetermined term energies for the $a^{2} \Phi_{7 / 2}$ and $a^{2} \Phi_{5 / 2}$ spin components, respectively.
molecular constants for the $a^{2} \Phi,[7.3]^{2} \Delta$ and $[9.4]^{2} \Phi$ states are provided in Table 3.

## RESULTS AND DISCUSSION

The constants of Table 3 clearly indicate the presence of interactions in the two spin components of the lower $a^{2} \Phi$ state. The molecular constants for the $\mathrm{v}=2$ and 3 vibrational levels of the $a^{2} \Phi_{7 / 2}$ and $a^{2} \Phi_{5 / 2}$ spin components indicate that these levels are affected by strong global interactions. Although no local perturbations have been observed in these vibrational levels, the vibrational intervals as well as the $B_{v}$ and $D_{\mathrm{v}}$ constants have abnormal magnitudes. For example, the vibrational intervals of $\Delta G(1 / 2)=411.42811(49) \mathrm{cm}^{-1}, \Delta G(3 / 2)=$ $407.1793(67) \mathrm{cm}^{-1}, \Delta G(5 / 2)=411.7237(73) \mathrm{cm}^{-1}, \Delta G(7 / 2)=$ $401.6292(32) \mathrm{cm}^{-1}$, and $\Delta G(9 / 2)=400.5090(13) \mathrm{cm}^{-1}$ for the $a^{2} \Phi_{7 / 2}$ spin component and $\Delta G(1 / 2)=411.30660(31) \mathrm{cm}^{-1}$, $\Delta G(3 / 2)=408.38659(46) \mathrm{cm}^{-1}, \Delta G(5 / 2)=410.1215(16)$, and $\Delta G(7 / 2)=404.8471(21) \mathrm{cm}^{-1}$ for the $a^{2} \Phi_{5 / 2}$ spin component have been observed. Similar irregular variations have been found for the rotational and distortion constants. Therefore, meaningful equilibrium molecular constants could not be determined for the $a^{2} \Phi$ state although approximate values of $\omega_{e}$
$=413.8952 \mathrm{~cm}^{-1}, \omega_{e} x_{e}=1.2336 \mathrm{~cm}^{-1}, B_{e}=0.12836 \mathrm{~cm}^{-1}$, and $\alpha_{e}=0.00054 \mathrm{~cm}^{-1}$ were estimated for the $\mathrm{a}^{2} \Phi_{7 / 2}$ spin component by deweighting the values corresponding to the perturbed levels. The values of $\omega_{e}=413.0669 \mathrm{~cm}^{-1}, \omega_{e} x_{e}=$ $0.8801 \mathrm{~cm}^{-1}, B_{e}=0.12836 \mathrm{~cm}^{-1}$, and $\alpha_{e}=0.00064 \mathrm{~cm}^{-1}$ were estimated for the $a^{2} \Phi_{5 / 2}$ spin component in a similar manner. The constants for the $[7.3]^{2} \Delta_{3 / 2}$ spin component, for which $v=0$ and 1 vibrational levels have been observed, have the values of $\Delta G(1 / 2)=362.64732(78) \mathrm{cm}^{-1}, \quad B_{e}=$ $0.1187052(10)$, and $\alpha_{e}=0.0005062(12) \mathrm{cm}^{-1}$.

In contrast to the $a^{2} \Phi$ state, the constants for the $[9.4]^{2} \Phi$ state indicate that this state is free from perturbations. For example, the regular intervals of $\Delta G(1 / 2)=353.69517(42)$ $\mathrm{cm}^{-1} \Delta G(3 / 2)=351.41732(47) \mathrm{cm}^{-1}$ and $\Delta G(5 / 2)=$ $349.14097(89) \mathrm{cm}^{-1}$ have been obtained for the $[9.4]^{2} \Phi_{72}$ spin component. This provides $\omega_{e}=355.97225(70) \mathrm{cm}^{-1}$, and $\omega_{e} x_{e}$ $=1.13864(20) \mathrm{cm}^{-1}$ for the $[9.4]^{2} \Phi_{7 / 2}$ spin component. The rotational constants for the different vibrational levels of the $[9.4]^{2} \Phi_{7 / 2}$ spin component are also very regular and provide the equilibrium constants of $B_{e}=0.11931542(52) \mathrm{cm}^{-1}$ and $\alpha_{e}=$ $0.00053822(24) \mathrm{cm}^{-1}$. The molecular constants for the $[9.4]^{2} \Phi_{5 / 2}$ spin component (Table 3) also do not show the
influence of perturbations and provide the equilibrium constants of $\omega_{e}=354.79904(30) \mathrm{cm}^{-1}, \omega_{e} x_{e}=1.14019(38) \mathrm{cm}^{-1}$, $B_{e}=0.11912290(38) \mathrm{cm}^{-1}$, and $\alpha_{e}=0.00053987(17) \mathrm{cm}^{-1}$ for the $[9.4]^{2} \Phi_{5 / 2}$ spin component.

Prior to our very recent work on ZrCl (5), there were very limited spectroscopic studies. The initial studies of ZrCl had suggested a ${ }^{4} \Sigma^{-}$ground state for $\mathrm{ZrCl}(1,2)$, while our recent analysis of an infrared transition has suggested a ${ }^{4} \Phi$ ground state (5) consistent with experimental observations for isovalent TiCl (6) and TiF (7). This observation has recently been supported by theoretical calculations of Focsa et al. for TiCl (13) and ZrCl (14). These calculations have also predicted the location of some states in the doublet manifold. In particular, they have predicted a ${ }^{2} \Phi$ state located at $4810 \mathrm{~cm}^{-1}$ above the ground $X^{4} \Phi$ state is the first doublet excited state of ZrCl (14). The lower $a^{2} \Phi$ state observed in the present work is, therefore, the first excited doublet state of ZrCl . Three more low-lying doublet states ${ }^{2} \Sigma^{-},{ }^{2} \Pi$, and ${ }^{2} \Delta$ have been predicted at 6931 $\mathrm{cm}^{-1}, 7935 \mathrm{~cm}^{-1}$, and $8886 \mathrm{~cm}^{-1}$ by the ligand field calculations of Focsa et al. (14). The ${ }^{2} \Delta$ state observed in our spectrum near $7300 \mathrm{~cm}^{-1}$ can tentatively be assigned as the ${ }^{2} \Delta$ state calculated by Focsa et al. (14) near $8886 \mathrm{~cm}^{-1}$ above the ground state. The location of the $[9.4]^{2} \Phi$ state has not been calculated by Fosca et al. (14) because it arises from a higher atomic configuration. High-quality $a b$ initio calculations are necessary to confirm our assignments and the ligand field predictions. A reliable prediction of the spectroscopic properties of ZrCl will require the use of high-level ab initio calculations using large basis sets and an extensive treatment of electron correlation.

Our electronic assignments must be regarded as tentative since first lines were not measured. The most likely alternative assignments of $[7.3]^{2} \Phi-a^{2} \Delta$ and $[9.4]^{2} \Delta-a^{2} \Delta$ for our two electronic transitions cannot be ruled out yet.

We have noticed several small errors in the work of Phillips et al. (4). In particular the J assignment in the $1-3$ band of the $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ subband [their notation, ${ }^{2} \Pi_{3 / 2}{ }^{-2} \Pi_{3 / 2}$ ] needs to be increased by 2 units. It is worth mentioning that they stated in their paper that the $P$ branch was not observed in the 1-3 band, while we have observed both $R$ and $P$ branches. We have also noticed that the $J$ assignment in the $0-1,0-0$ and the $1-0$ bands of the $[9.4]^{2} \Phi_{7 / 2}-a^{2} \Phi_{7 / 2}$ subband [their notation, ${ }^{2} \Pi_{1 / 2}-$ $\left.{ }^{2} \Pi_{1 / 2}\right]$ needs to be increased by one unit, but this could be a misprint since the constants reported for this subband match very well with the values obtained in the present analysis.

## CONCLUSIONS

The near infrared emission spectrum of ZrCl has been observed at high resolution using a Fourier transform spectrom-
eter. Numerous new bands have been detected in the $6700-$ $12000 \mathrm{~cm}^{-1}$ region in addition to those reported previously by Phillips et al. (4). Six new bands observed near 9838, 9776, $8315,8257,7855$, and $7806 \mathrm{~cm}^{-1}$ have been identified as $2-0$, $3-1,0-2,1-3,1-4$ and $2-5$ bands of the $[9.4]^{2} \Phi_{7 / 2}-a^{2} \Phi_{7 / 2}$ subband while additional new bands observed near 9137, 8727, 8375 and $8325 \mathrm{~cm}^{-1}$ have been identified as $1-2,1-3,0-3$ and $1-4$ bands of the $[9.4]^{2} \Phi_{5 / 2}-a^{2} \Phi_{5 / 2}$ subband. To lower wavenumbers, the bands found near 6835 and $7246 \mathrm{~cm}^{-1}$ have been assigned as the $0-1$ and $0-0$ bands of the $[7.3]^{2} \Delta_{5 / 2}-a^{2} \Phi_{7 / 2}$ subband and bands near 6940, 7351 , and $7714 \mathrm{~cm}^{-1}$ have been assigned as the $0-1,0-0$, and $1-0$ bands of the $[7.3]^{2} \Delta_{3 / 2}-$ $a^{2} \Phi_{5 / 2}$ subband. Both of these transitions have the lower state in common. A rotational analysis of these bands has been obtained and molecular constants have been determined. The nature of the observed states has been discussed in light of the available theoretical results, but more calculations are needed.

## ACKNOWLEDGMENTS

We thank J. Wagner and C. Plymate of the National Solar Observatory for assistance in obtaining the spectra. The National Solar Observatory is operated by the Association of Universities for Research in Astronomy, Inc., under contract with the National Science Foundation. The research described here was supported by funding from NASA laboratory astrophysics program. Some support was also provided by the Petroleum Research Fund administered by the American Chemical Society and the Natural Sciences and Engineering Research Council of Canada.
