#### Abstract

Six new electronic transitions of NiCl , recorded by high-resolution Fourier transform spectroscopy, have been studied. The identification of the states involved in these transitions has been made possible by dispersing laser-induced fluorescence at low resolution. Comparison of the results obtained using these two experimental techniques allowed us to locate the [1.6] $A^{2} \Delta_{3 / 2}$ ( $v=0$ ) spin-orbit component at $1646 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ ground state. Two other low-lying states have also been identified: the first one, located $382 \mathrm{~cm}^{-1}$ above the ground state is a good candidate to be the $X^{2} \Pi_{1 / 2}$ component of the $X^{2} \Pi_{i}$ state. A second state at $1385 \mathrm{~cm}^{-1}$ in the energy level diagram could be a component of a quartet state of NiCl . In addition we have identified a $\Omega=3 / 2$ state $21608 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ ground state. The [22.3] ${ }^{2} \Delta_{3 / 2}$ spin-orbit component associated with already known $[21.9]^{2} \Delta_{5 / 2}$ sublevel has also been identified. © 2001 Elsevier Science

## I. INTRODUCTION

In two recent papers $(1,2)$ devoted to the analysis of the visible spectrum of NiCl , we demonstrated the complementarity of low-resolution laser-induced dispersed fluorescence experiments and Fourier transform spectroscopy. NiCl is similar to the isovalent molecule NiF (3), so three low-lying electronic states $\left({ }^{2} \Pi_{i},{ }^{2} \Delta_{i}\right.$, and $\left.{ }^{2} \Sigma^{+}\right)$are expected in the first $2000 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ ground state. This causes an impressive number of intense (allowed) and weak (forbidden) transitions connecting to several upper electronic states. In addition, intervals between the electronic states are, in some cases, close to the values of the vibrational spacing. This can lead to mistakes in the identification of the electronic states linked by the observed transitions (4). Even when a rotational analysis is possible, it can happen that two close-lying states have almost equal rotational and fine structure constants, leading to erroneous identifications of the electronic states. It appears that the construction of a credible energy level diagram can be carried out by observation of dispersed laser-induced fluorescence. Such an energy level diagram is a useful starting point to study bands recorded at high resolution either by (time-consuming) laser excitation spectroscopy (5) or by (time-saving) Fourier transform spectroscopy (1, 2).

In this paper, we present the analysis of bands involving $[1.6] A^{2} \Delta_{3 / 2}$ spin-orbit component and the already known $[24.9]^{2} \Pi_{1 / 2},[24.5]^{2} \Pi_{3 / 2},[21.9]^{2} \Delta_{5 / 2}$ states as well as a new [21.6] $\Omega=3 / 2$ electronic state. In addition a [22.3] ${ }^{2} \Delta_{3 / 2}$ sublevel located at $22362 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ state can be associated with the already known [21.9] ${ }^{2} \Delta_{5 / 2}$ spin-orbit component (1). We locate on the energy level diagram the
$[0.38]^{2} \Pi_{1 / 2}$ state and an electronically unassigned low-lying state $1385 \mathrm{~cm}^{-1}$ above the ground $X^{2} \Pi_{3 / 2}$ state.

## II. EXPERIMENTAL DETAILS

Details about the experimental setups have been extensively described in Refs. (1) and (2). We just recall that in the laserinduced fluorescence experiments, heated nickel vapor reacts with $\mathrm{CH}_{3} \mathrm{Cl}$ to produce NiCl molecules which interact with a cw tunable laser beam. The resultant fluorescence is dispersed with a Jobin-Yvon spectrometer. The Fourier transform spectra were recorded with a Bruker IFS 120 HR spectrometer with emission induced by a $2450-\mathrm{MHz}$ microwave discharge exciting a continuous flow of heated $\mathrm{NiCl}_{2}$ vapor and He buffer gas in a quartz tube.

## III. DESCRIPTION OF THE BANDS

The strong ionicity of halide compounds forces the low-lying molecular electronic configurations to be centered on the $3 d$ atomic orbital of the metal atom. In the case of NiCl , as for NiF , the ${ }^{2} \Sigma^{+},{ }^{2} \Pi_{i}$, and ${ }^{2} \Delta_{i}$ states corresponding to the $3 d \sigma^{-1}$, $3 d \pi^{-1}$, and $3 d \delta^{-1}$ electron holes are expected to be low-lying in the energy level diagram. In previous papers ( 1,2 ), some of the spin components associated with these three terms have been identified (see Fig. 1 of Ref. 2).
Laser-induced dispersed fluorescence experiments have been performed. The three already known upper electronic spinorbit components $[24.9]^{2} \Pi_{1 / 2}(v=0),[24.5]^{2} \Pi_{3 / 2}(v=0)$, and $[21.9]^{2} \Delta_{5 / 2}(v=0)$ were populated using a dye laser and we

FIG. 1. Energy level diagram of NiCl: Full lines: analyzed allowed transitions. Dashed lines: analyzed forbidden transitions. Dotted lines: observed transitions. All entries are in $\mathrm{cm}^{-1}$.
systematically recorded the induced fluorescence. Beside some $0-1$ vibrational bands these experiments led to the identification of five transitions linking two or three of the upper states to two low-lying states located at $1646 \mathrm{~cm}^{-1}$ and $382 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ state (Fig. 1). The low-resolution data was compared with observations of the bands recorded by Fourier transform spectroscopy.

From these considerations it has been possible to determine that the $\Omega=3 / 2$ state located at $1646 \mathrm{~cm}^{-1}$ in the energy level diagram is the $[1.6]^{2} \Delta_{3 / 2}$ spin-orbit component of the $A^{2} \Delta_{i}$ state associated with the $[0.16]^{2} \Delta_{5 / 2}$ sublevel located at $161 \mathrm{~cm}^{-1}$. Because of the correlation between the molecular orbitals and the $3 d$ orbital of $\mathrm{Ni}^{+}$, it is expected that the spinorbit splitting ( $1485 \mathrm{~cm}^{-1}$ ) of the $A^{2} \Delta_{i}$ is about twice the value of the atomic spin-orbit coefficient ( $\xi=603 \mathrm{~cm}^{-1}$ ) of the [ $\left.3 d^{9}\right]^{2} D$ ground state of $\mathrm{Ni}^{+}(6)$. Considering the interactions possible between the close-lying $B^{2} \Sigma^{+}, X^{2} \Pi_{i}$, and $A^{2} \Delta_{i}$ states, the agreement between the experimental value $\left(1485 \mathrm{~cm}^{-1}\right)$ and
the theoretical one $\left(1206 \mathrm{~cm}^{-1}\right)$ is convincing. We also note that this value agrees also with the spin-orbit splitting of the $A^{2} \Delta_{i}$ state of NiF which is equal to $1394 \mathrm{~cm}^{-1}$.

It is tempting to use the same kind of arguments for the $\Omega=1 / 2$ state located at $382 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ component of the ground state. The spin-orbit splitting, in the case of a ${ }^{2} \Pi$ state, must be equal to the value of the spin-orbit coefficient of the ground state of $\mathrm{Ni}^{+}$. The discrepancy is almost $40 \%$ and the identity of the new state must be confirmed by rotational analysis. Note that in the case of NiF, the $X^{2} \Pi_{1 / 2}$ state has not been identified but that a so-called ${ }^{2} \Sigma^{+}$state, located $251 \mathrm{~cm}^{-1}$ above the ground, has been rotationally analyzed (7, 8).

Regardless of the symmetry attributed to the $\Omega=1 / 2$ sublevel located $382 \mathrm{~cm}^{-1}$ above the $X^{2} \Pi_{3 / 2}$ state, we have now a good knowledge of the relative position of the doublet states appearing in the first $2000 \mathrm{~cm}^{-1}$ above the ground state of NiCl . Scanning the laser to the red side of the [21.9] ${ }^{2} \Delta_{5 / 2}(v=0)-$ $[0.16] A^{2} \Delta_{5 / 2}(v=0)$ transition located at $21744 \mathrm{~cm}^{-1}(1)$, we observed an intense fluorescence signal when the laser excited a strong $R$ head ( $21610 \mathrm{~cm}^{-1}$ ). A survey scan of the spectral region to lower wavenumbers showed that fluorescence signals were observed at $21450 \mathrm{~cm}^{-1}, 21230 \mathrm{~cm}^{-1}$, $19967 \mathrm{~cm}^{-1}$, and $19844 \mathrm{~cm}^{-1}$. It was then easy to conclude that a state located at about $21608 \mathrm{~cm}^{-1}$ in the energy level diagram was populated and that we recorded laser-induced fluorescence down to all the known low-lying states of NiCl . Selection rules do not provide information on the nature of the new upper state because a comparison of intensities of the bands recorded by Fourier transform spectroscopy is not convincing. Rotational analysis of three transitions sharing this new upper state allowed us to identify it as a $\Omega=3 / 2$ component. In the separate set of experiments, the fluorescence signals, selection rules and the patterns of emission did allow us to ascertain that the upper state of three transitions located at $22370 \mathrm{~cm}^{-1}, 21987 \mathrm{~cm}^{-1}$, and $20723 \mathrm{~cm}^{-1}$ is the $[22.3]^{2} \Delta_{3 / 2}$ spin-orbit component associated with the known $[21.9]^{2} \Delta_{5 / 2}$ state.

## IV. ROTATIONAL ANALYSIS OF THE BANDS

## (a) Introduction

A characteristic of the emission spectrum of NiCl recorded in the spectral region of $20000-25000 \mathrm{~cm}^{-1}$ is that only two bands $[21.9]^{2} \Delta_{5 / 2}(v=0)-[0.16] A^{2} \Delta_{5 / 2}(v=0)$ and $[21.9]^{2} \Delta_{5 / 2}$ $(v=0)-X^{2} \Pi_{3 / 2}(v=0)$ have a very good signal-to-noise ratio (see Fig. 1 of Ref. 1), although the other bands also display rotational structure. As a consequence analyses of the bands described hereafter have been carried out simultaneously to allow the comparison of combination differences of common states. In addition, Professor Tanimoto at Shizuoka University $(9,10)$ provided very accurate rotational parameters derived from microwave experiments for the $X^{2} \Pi_{3 / 2}(v=0)$ and the
$[0.16]^{2} \Delta_{5 / 2}(v=0)$ substates. These values have been used as fixed parameters in the fits.

> (b) The $[24.9]^{2} \Pi_{l / 2}-[1.6] A^{2} \Delta_{3 / 2}$ and $[24.5]^{2} \Pi_{3 / 2}$
> $-[1.6] A^{2} \Delta_{3 / 2}$ Transitions

Up to now, four transitions from the spin-orbit components of the upper ${ }^{2} \Pi_{i}$ state have been studied, and two of them allowed us to determine the rotational and fine structure parameters of the $[1.7] B^{2} \Sigma^{+}(v=0)$ state (2). Our new data shows that the two components of the upper ${ }^{2} \Pi_{i}$ state are also linked to the $[1.6] A^{2} \Delta_{3 / 2}$ substate. Qualitative observation of the emission spectrum shows that the $[24.9]^{2} \Pi_{1 / 2}-[1.6] A^{2} \Delta_{3 / 2}$ transition is an allowed transition (with $Q$ branches), while the $[24.5]^{2} \Pi_{3 / 2}-$ $[1.6] A^{2} \Delta_{3 / 2}$ is a weak forbidden transition (without a $Q$ branch). The wavenumbers of the experimental lines of these two new transitions have been included in a fit along with the four previously studied transitions (2). In the fitting procedure, the same matrix used previously (2) for the upper ${ }^{2} \Pi_{i}$ state was employed, while a polynomial expression (1) was used to describe the two widely separated components of the $A^{2} \Delta_{i}$ state. Experimental lines are listed in Table 1 and the derived parameters in Table 2. We note that it has been possible to determine the $\Lambda$-doubling parameter $q$ in the upper ${ }^{2} \Pi_{i}$ state in this study. In the previous analysis (2), the excited ${ }^{2} \Pi_{1 / 2}$ was only connected to the $[1.7] B^{2} \Sigma^{+}(v=0)$ state. However, in this transition only four of the six expected branches were identified, hence there was a strong correlation between the parameter $q$ and the spinrotation parameter $\gamma_{D}$ of the [1.7] $B^{2} \Sigma^{+}$state. In the present fit, the forbidden $[24.5]^{2} \Pi_{3 / 2}-[1.6] A^{2} \Delta_{3 / 2}$ transition gave a good value for the effective $\Lambda$-doubling parameter $p_{D}$ of the $[1.6] A^{2} \Delta_{3 / 2}$ lower state. The variance of the fit was significantly improved by the presence of the parameter $q$ in the upper ${ }^{2} \Pi_{1 / 2}$ state.
(c) The $[21.9]^{2} \Delta_{5 / 2}(v=0)-[1.6] A^{2} \Delta_{3 / 2}(v=0)$ Transition

This transition is the only forbidden one that we found involving the upper [21.9] ${ }^{2} \Delta_{5 / 2}$ state. The presence of $Q$ branches is characteristic of a $\Delta \Omega \neq 0$ transition as expected. In a first step we calculated the wavenumbers for the rotational lines based on the parameters determined in the previous section for the [1.6] $A^{2} \Delta_{3 / 2}$ state and those in Ref. 1 for the $[21.9]^{2} \Delta_{5 / 2}(v=0)$ state and we picked out the lines of the six branches in the experimental spectrum recorded by Fourier transform spectroscopy. Then (as for the previous set of bands) the lines were fitted along with the $0-$ 0 bands of the $[21.9]^{2} \Delta_{5 / 2}-[0.16] A^{2} \Delta_{5 / 2}$ and [21.9] ${ }^{2} \Delta_{5 / 2}-$ $X^{2} \Pi_{3 / 2}$ transitions (1) fixing the parameters for the two lower states to the values determined by Yamazaki et al. (9, 10).

We found a mistake in Table 3 of Ref. 1: the lines listed for the $Q_{e f}$ branch of the $[21.9]^{2} \Delta_{5 / 2}(v=0)-X^{2} \Pi_{3 / 2}(v=0)$ are not corrected by the calibration factor. All the entries of this
column must be multiplied by the factor 1.000002 23. This has no consequence for the derived parameters, which were fitted with correct wavenumbers in Ref. I.

## (d) The $[21.6] \Omega=3 / 2$ Electronic State <br> and Linked Transitions

As observed for the $[24.5]^{2} \Pi_{3 / 2}$ state, the new $[21.6] \Omega=3 / 2$ state is involved in transitions that connect to all the identified components of the low-lying doublet states. The intense [21.6] $\Omega=3 / 2-X^{2} \Pi_{3 / 2}$ transition observed at $21608 \mathrm{~cm}^{-1}$ has been directly studied. The $J$-numbering of the lines was easily determined thanks to the usual combination relationships associated with the good constants available for the ground state (9). No fine structure was found in the upper state. Next the weak $[21.6] \Omega=3 / 2-[0.16] A{ }^{2} \Delta_{5 / 2}$ and [21.6] $\Omega=3 / 2-[0.16] A$ ${ }^{2} \Delta_{3 / 2}$ transitions were predicted to make the identification of the experimental lines easy, and finally the lines of the three transitions sharing the upper [21.6] $\Omega=3 / 2$ state were fitted by constraining the constants of the $X^{2} \Pi_{3 / 2}$ and $[0.16] A^{2} \Delta_{5 / 2}$ states to the values determined from microwave data $(9,10)$. All the lines are listed in Table 1 and the derived parameters in Table 2.

No efforts were made to analyze the very weak [21.6] $\Omega=3 / 2-[1.7] B^{2} \Sigma^{+}$transition ( $19840 \mathrm{~cm}^{-1}$ ) in which the rotational structure was not resolved because of the poor signal-to-noise ratio. In addition, some information about the position of bands involving higher vibrational levels of the studied states is collected in Table 3. From this list of bandhead positions, it is possible to determine approximately the vibrational parameters of the $[21.6] \Omega=3 / 2$ state $\left(\omega_{e}=406.1(2) \mathrm{cm}^{-1}\right.$, $\left.\omega_{e} x_{e}=2.6(2) \mathrm{cm}^{-1}\right)$ and the $\Delta G_{1 / 2}$ value of the [1.6] $A^{2} \Delta_{3 / 2}$ state $\left(\Delta G_{1 / 2}=429.9(5) \mathrm{cm}^{-1}\right)$.

## (e) The $[22.3]^{2} \Delta_{3 / 2}$ State and the Linked Transitions

The number of unassigned bands between 20000 and $25000 \mathrm{~cm}^{-1}$ are now rather few. Most of them are not fully resolved but the bandheads are clearly visible. The correctness of the pattern that we suggest for the low-lying states can be confirmed by identifying new upper states linked to some of the components of the $X, A$, and $B$ states.

In the course of the work described in the previous section we identified some vibrationally-excited bands, among which is the $[21.6] \Omega=3 / 2(v=2)-X^{2} \Pi_{3 / 2}(v=1)$ one $\left(21988 \mathrm{~cm}^{-1}\right)$. In the emission spectrum this band is significantly stronger than the $1-0$ band ( $22014 \mathrm{~cm}^{-1}$ ) of the same transition. We suspected that another band overlapped with the $2-1$ band. Tuning the laser to this spectral region, we observed two weak fluorescence signals ( $R$-heads) at $20723 \mathrm{~cm}^{-1}$ and $22370 \mathrm{~cm}^{-1}$. A new upper state is therefore located at about $22364 \mathrm{~cm}^{-1}$, and this state is involved in three transitions connecting to the [1.6] $A^{2} \Delta_{3 / 2}$ state (band head observed at $20723 \mathrm{~cm}^{-1}$ ), the [0.38] $X^{2} \Pi_{1 / 2}$ state (band head at $21988 \mathrm{~cm}^{-1}$, which overlaps

with the [21.6] $\Omega=3 / 2(v=2)-X^{2} \Pi_{3 / 2}(v=1)$ band) and the $X^{2} \Pi_{3 / 2}$ state (bandhead at $22370 \mathrm{~cm}^{-1}$ ). In addition, weak fluorescence involving the $[0.16] A^{2} \Delta_{5 / 2}$ state was observed at $22201 \mathrm{~cm}^{-1}$, but efforts made to observe a transition to the $[1.7] B^{2} \Sigma^{+}$state remained unsuccessful.

A rotational analysis of the band located at $20723 \mathrm{~cm}^{-1}$ was partially successful thanks to the good knowledge of the $B$ rotational constant of the [1.6] $A^{2} \Delta_{3 / 2}$ state (Table 2). Unfortunately it has not been possible to determine any fine structure parameter because of the lack of high $J$-value rotational lines. The constants of the $X^{2} \Pi_{3 / 2}$ state are very well known (1,9), so a simulated set of lines of the $R$-branch located at $22364 \mathrm{~cm}^{-1}$ reproduced the position of the head with an uncertainty of $0.2 \mathrm{~cm}^{-1}$. This new state is located at $T_{0}=22364.4 \mathrm{~cm}^{-1}$, i.e., $459.2 \mathrm{~cm}^{-1}$ above the [21.9] ${ }^{2} \Delta_{5 / 2}$ state. Four arguments can be given to suggest that this new state is the ${ }^{2} \Delta_{3 / 2}$ spin-orbit component of a ${ }^{2} \Delta_{i}$ state associated with the [21.9] ${ }^{2} \Delta_{5 / 2}$ state. First the rotational constants are rather similar (Table 2); second this state is not linked to the $[1.7] B^{2} \Sigma^{+}$state; third there are
no $Q$-branches in the $\Delta \Omega=0$ transitions $[21.3]^{2} \Delta_{3 / 2}-$ $[1.6] A^{2} \Delta_{3 / 2}\left(20718 \mathrm{~cm}^{-1}\right)$ and [21.3] ${ }^{2} \Delta_{3 / 2}-X^{2} \Pi_{3 / 2}$ ( $21982 \mathrm{~cm}^{-1}$ ). Finally, assuming that this new state is a ${ }^{2} \Delta_{3 / 2}$ spin-orbit component, the spin-orbit interval is $459 \mathrm{~cm}^{-1}$, in agreement with predictions based on the atomic spin-orbit constant. As for the lower energy states, a strong correlation between the molecular orbitals and the atomic orbitals of $\mathrm{Ni}^{+}$can be assumed. In the case of NiF, Carette et al. (6) located a group of states between $17500 \mathrm{~cm}^{-1}$ and $21500 \mathrm{~cm}^{-1}$ in the energy level diagram, associated with the $\left[3 d^{8} 4 s\right]^{2} D$ electronic state of $\mathrm{Ni}^{+}$. The spin-orbit coefficient of this state is $\xi=275 \mathrm{~cm}^{-1}$ (6). As noted in Section III, a ${ }^{2} \Delta_{i}$ electronic state should exhibit a spinorbit splitting equal to $2 \xi=550 \mathrm{~cm}^{-1}$, which is in agreement with the experimental value $\left(459 \mathrm{~cm}^{-1}\right)$.

## V. DISCUSSION AND CONCLUSION

By combining the results collected from two experimental methods has made it possible to draw an energy level diagram

TABLE 2

${ }^{a}$ The [1.6] $A^{2} \Delta_{3 / 2}$ has been described by a polynomial expression:

$$
T=T_{0}+B_{0} J(J+1)-D_{0} J^{2}(J+1)^{2} \pm(1 / 2) p_{D} J(J+1)(J+0.5),
$$

the + and - refer to the $e$ and $f$ parity levels respectively.
${ }^{b}$ Estimated constants. See text.
of the low-lying $X^{2} \Pi_{i}, A^{2} \Delta_{i}$, and $B^{2} \Sigma^{+}$states of NiCl (Fig. 1). If we compare this diagram to that of NiF (3), we note that in both cases the ground state is a $X^{2} \Pi_{3 / 2}$ spin-orbit component. The $B^{2} \Sigma^{+}$states are located at $1768 \mathrm{~cm}^{-1}(\mathrm{NiCl})$ and at $1574 \mathrm{~cm}^{-1}$ ( NiF ), the $A^{2} \Delta_{5 / 2}$ and $A^{2} \Delta_{3 / 2}$ substates are observed, respectively, at 161 and $1646 \mathrm{~cm}^{-1}(\mathrm{NiCl})$ and 830 and $2224 \mathrm{~cm}^{-1}$ (NiF).

The identification of the $X^{2} \Pi_{1 / 2}$ spin-orbit component is very puzzling for NiCl as well as for NiF . In the case of NiF a state located $251 \mathrm{~cm}^{-1}$ above the ground state has been described as a ${ }^{2} \Sigma^{+}$state (7) and a large value ( $\gamma=-0.9 \mathrm{~cm}^{-1}$ ) of the spin-rotation parameter as been determined. This analy-

sis was possible only with the help of selective excitation using a high-resolution laser. The description of this state has been recently confirmed by Tanimoto et al. (8). For the two expected $\Omega=1 / 2$ low-lying states we found two ${ }^{2} \Sigma^{+}$states rather than a ${ }^{2} \Sigma^{+}$state and a ${ }^{2} \Pi_{1 / 2}$ state as expected from the $3 d$-centered atomic orbital model. In Ref. 6 a ligand field theory interpretation of the molecular electronic energy levels of NiF showed that the first $\Omega=1 / 2$ state is a mixture of two electronic configurations ( $67 \%$ of ${ }^{2} \Pi_{1 / 2}$ state and $33 \%$ of ${ }^{2} \Sigma^{+}$ state), which could be responsible for the unusual behavior of the so-called ${ }^{2} \Sigma^{+}$state lying at $251 \mathrm{~cm}^{-1}$ above the ground state of NiF .

It turns out that in the case of NiCl the situation is similar. The $[0.38]^{2} \Pi_{1 / 2}$ state is involved in four intense transitions to the $[21.6] \Omega=3 / 2$, the $[22.3]^{2} \Delta_{3 / 2}$, the $[24.5]^{2} \Pi_{3 / 2}$, and the [24.9] ${ }^{2} \Pi_{1 / 2}$ upper states. Up to now, however, attempts to analyze these bands have been unsuccessful despite the fact that the upper states of the transitions are now well known. Such a problem of interpretation also occurs in the analysis of the microwave data (11). It seems that, as observed for NiF , the [0.38] $X^{2} \Pi_{1 / 2}$ spin component is affected by a strong interaction with close-lying states. Despite the congested aspect of the bands we hope to be able to carry out laser experiments as was done successfully in the case of NiF (7).

In general, the energy levels of metal halides $(M X, X=\mathrm{F}, \mathrm{Cl}$, $\mathrm{Br}, \mathrm{I})$ correlate with those of metal hydrides $(M \mathrm{H})$. However, the low-lying electronic energy levels of NiH appear to differ somewhat from those of the nickel halides. For NiH , the ground state is a ${ }^{2} \Delta$ state and the second and third lowest states are ${ }^{2} \Sigma^{+}$ and ${ }^{2} \Pi$, respectively (12), while NiF and NiCl have ${ }^{2} \Pi$ ground states.

In Section III, it was mentioned that the spin-orbit splitting of the $X^{2} \Pi$ and $A^{2} \Delta$ states did not match very well with the predicted values from the $\mathrm{Ni}^{+}$atomic value ( $603 \mathrm{~cm}^{-1}(6)$ ). Field and his co-workers (12) pointed out that the low-lying
electronic states of NiH severely interact, resulting in large energy level shifts. This complex interaction consists of the spinorbit interaction due to the $3 d$-electron hole on the $\mathrm{Ni}^{+}$atom, rotation-electronic interaction because of the large molecular rotational constant, and accidental perturbations arising when vibrational energy level separations in the $X^{2} \Pi$ and $A^{2} \Delta$, and $B^{2} \Sigma^{+}$states happen to match the electronic term values of the $A^{2} \Delta$ and $B^{2} \Sigma^{+}$states. The same interaction scheme should be considered for NiF and NiCl . However, the rotation-electronic and vibrational interactions from the "supermultiplet" model (12) are negligible for the heavier NiF and NiCl . Thus, the spinorbit intervals in the $X^{2} \Pi$ and $A^{2} \Delta$ states are strongly affected by off-diagonal spin-orbit interactions among low-lying states: $X^{2} \Pi_{3 / 2}$ shifts $A^{2} \Delta_{3 / 2}$ up and $X^{2} \Pi_{1 / 2}$ is lowered by $B^{2} \Sigma^{+}$. This is consistent with the fact that the effective molecular spinorbit coupling constant of the $X^{2} \Pi$ state $\left(\left|A_{0}\right| \sim 382 \mathrm{~cm}^{-1}\right)$ is reduced, but that of $A^{2} \Delta\left(\left|A_{0}\right| \sim 742 \mathrm{~cm}^{-1}\right)$ state is larger than the prediction $\left(\left|A_{0}\right| \sim 603 \mathrm{~cm}^{-1}\right)$ from the $\mathrm{Ni}^{+}$atom.

One remaining problem is the presence of a sixth low-lying state located at about $1385 \mathrm{~cm}^{-1}$ on the energy level diagram. This state is involved in an intense transition located at $20225 \mathrm{~cm}^{-1}$ which can be seen in emission when the laser line populates the $[21.6] \Omega=3 / 2$ state. Similarly a weak fluorescence is observed at $20250 \mathrm{~cm}^{-1}$, when the laser populates the $[21.9]^{2} \Delta_{5 / 2}$ state. We suspect that this new low-lying state to be a component of a quartet state. Carette et al. (6) showed that components of quartet states are theoretically expected in the first $2000 \mathrm{~cm}^{-1}$ above the ground state of NiF. Recently Chen et al. (13) carried out a molecular beam experiment on NiF. The temperature of the molecular beam is sufficiently low ( 90 K ) that only the two lowest energy spin components are populated. Laser excitation spectra are then free of transitions involving the other low-lying electronic states. We can hope that this experi-
mental technique (applied to NiCl ) could help to answer some of the remaining questions about the energy level diagram of NiCl .

## ACKNOWLEDGMENTS

We thank Professor M. Tanimoto at Shizuoka University for sharing his unpublished data. This work was supported by the Natural Sciences and Engineering Research Council of Canada (NSERC). The Centre d'Etudes et de Recherches Lasers et Applications is supported by the Ministère Chargé de la Recherche, the Région Nord-Pas de Calais, and the Fond Européen de Développement Economique des Régions.
